SHIGERU SATO

Trường Đại học Kitasato, Nhật Bản

Summary: During the years of 2006 - 2007, about five food poisoning cases with fatalities caused by marine snails reported in coastal areas of Vietnam. From stock over of poisoning materials from three out of five cases, causative species were identified as *Nassarius papillosus*, *Nassarius (Alectrion) glans glans*, *N. (Zeuxis) comptus* and *Natica (Natica) fasciata*. These species also caused poisonings in several countries such as Japan, the Philippines, Brunei and Taiwan.

High level of tetrodotoxin was found in the specimens of *N. papillosus* as the causative component for food poisoning with three patients including two deaths on October 17, 2006 in Quang Ngai province. In contrast, no tetrodotoxin was detected in three other snail species which were eaten at the poisonings on December 17, 2007 in Ninh Thuan province and December 27, 2007 in Binh Thuan province.

Although the origin of tetrodotoxin in marine snails has not been clarified yet, it is urgently necessary to warn potential risks from marine snails to public as some of them may become suddenly toxic with unknown mechanism.

Keywords: Poisonings, marine snails, *Nassarius*, *Natica*, tetrodotoxin.

I. INTRODUCTION

Among several marine snails, some species belonging to the genus *Conus* have been known as venomous as they cause envenomation by injecting toxins to human through sting (Halstead, 1988). In addition, some marine snails become toxic occasionally and cause human poisonings. Poisonings by eating marine snails were reported in Japan [Hashimoto, 1979], Philippines, Brunei (Meds, 2002), Malaysia (Kan *et al.*, 1986), Taiwan (Yang *et al.*, 1995) and French Polynesia (Gatti *et al.*, 2008). Most of the toxic species belong to *Turbinidae*, *Trotridae*, *Cymatidae*, *Olividae* and *Aplysiadae* families,

which were usually eaten, but become toxic accidentally, unexpectedly and occasionally in certain areas (Meds, 2002).

The responsible toxin in gastropods was reported as tetrodotoxin (TTX) and paralytic shellfish poisoning (PSP) toxins (Meds, 2002; Hwang *et al.* 2003). However, origin and mechanism of toxin accumulation in them have been not clear. Furthermore, not all individual of the same species, even caught at same location, possess toxicity. Individual variation of toxicity is very large.

During the years of 2006 - 2007, about five food poisoning cases with fatalities by marine snails were reported in coastal areas of Vietnam. Here we introduce the cases of food poisonings due to marine snails as well as preliminary result of toxin analysis from stock over of poisoning materials from three out of the five poisoning cases in Vietnam.

II. POISONING CASES

1. Case 1

On October 17, 2006, in Quang Ngai Province, three fishermen got poisoning after eating about 500 g of barbecued marine snails caught by themselves from the coastal areas. About 30 minutes after eating, all of them felt tingling on lips and mouth, difficult to breath and paralysis. Two victims in the same family died within two hours after showing the first symptom.

2. Case 2

On December 17, 2007, in Ninh Chu Village, Khanh Hai Commune, Ninh Hai Province, five peoples in one family including two children got poisoning after eating marine snails caught from coastal areas by themselves. All of them showed symptoms of dizziness, tingling on lips and tongue, and convulsion. They were sent to a hospital in time and recovered one day later.

3. Case 3

On December 27, 2007, in Duc Long Ward, Phan Thiet Town, Binh Thuan Province, four out of five peoples, who ate steamed marine snails caught from the coast, got poisoning and one of them died. Poisoning symptoms appeared 4 - 6 hours after eating were nausea, vomiting, dizziness, and tingling on tongue.

III. MATERIALS AND METHODS

1. Specimens of snails

Figure 1: Causative marine snails in Vietnam a: *Nassarius (Alectrion) papillosus*;
b: *Natica (Natica) fasciata*; c: *Nassarius (Alectrion) glans glans*;
d: *Nassarius (Zeuxis) compus*

Snail samples from three poisoning cases, one cooked specimen (5,6 g whole body) of *Nassarius papillosus* (fig. 1a) from poisoning case 1, 70 uncooked specimens of *Natica fasciata* (3.3 ± 0.5 g of whole body) (fig. 1b) from poisoning case 2, and three cooked specimens (2.7 ± 0.5 g of whole body) including one specimens of *Nassarius glans glans* (fig. 1c) and two specimens of *Nassarius compus* (fig. 1d) from poisoning case 3 were kept frozen, and sent to the Laboratory of Biochemistry, Institute of Oceanography, Nha Trang, Vietnam. Species identification was carried out.

2. Toxin analysis

Due to symptoms of victims which characterized by paralysis, toxin in these poisoning snails is highly suspected as TTX or PSP toxins, therefore these toxins are

targeted in our analysis. The soft tissue of each specimen was homogenized individually with 4 times volumes of 1% acetic acid, boiled for 5 minutes, and centrifuged (3000 g, 30 min). The supernatant thus obtained was used as the extract of which one mL is equivalent to 0.2 g of the tissue. TTX and its derivatives in the extracts were analyzed by HPLC according to Yotsu *et al.* (1989). PSP toxins were also analyzed by HPLC according to Oshima (1995). Authentic standard of TTXs (TTX, 4-*epi*TTX and 4,6-*anh*TTX mixture) was prepared from the toxic liver of Japanese puffer *Takifugu paradalis* (Kodama and Ogata, 1984). Standard PSP toxins containing C1+C2, GTX1-4 mixture, STX, dcSTX and neoSTX were a gift from Prof. Dr. Oshima of Tohoku University. The toxicity was calculated based on the specific toxicity of each TTX component (Nakamura and Yasumoto, 1985) and PSP toxins (Oshima, 1995), and express as mouse unit (MU) in which one MU is a toxin dose to kill a 20 g male mouse (ddY strain).

IV. RESULTS

1. Case 1

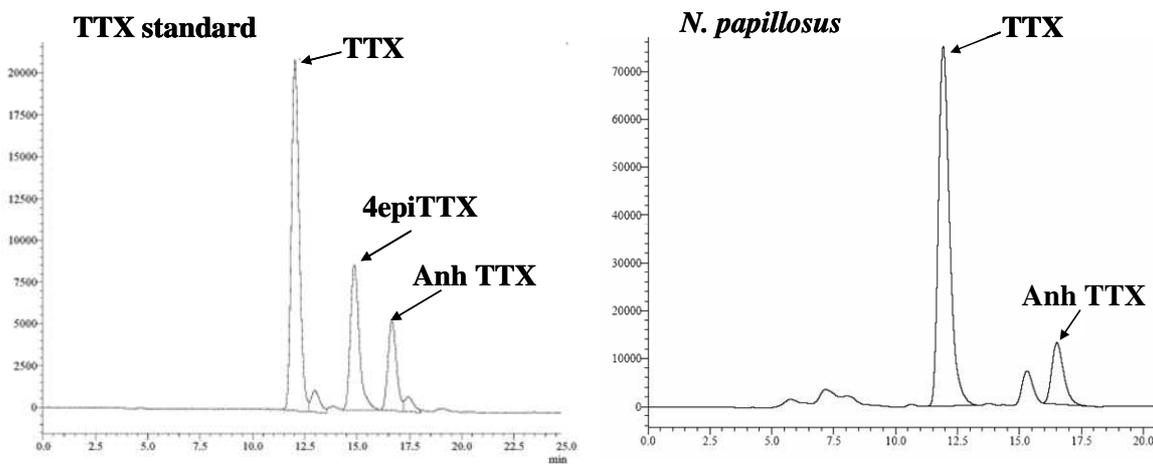

Figure 2: HPLC chromatogram of TTX in *N. papillosus*

No PSP toxin was detected in the extract, but TTX and *anhydro* TTX were detected by HPLC (fig. 2). The toxicity of the toxic specimen calculated from specific toxicity of each toxin component expressed in mouse unit (MU), was 70 MU/g soft tissues. In addition, there was a pick which showed a retention time closed to which of 4-epimer

TTX standard. However, the difference between this peak and 4-epimer TTX standard is larger than 2%, therefore, the peak was not recognized as 4-epimer TTX.

2. Case 2 and case 3

In HPLC analysis, low concentrations of TTXs and saxitoxins (STXs) were detected in the extracts. Toxicity calculated from HPLC results was less than 10 MU/g (data not shown in the paper).

V. DISCUSSION

TTX in gastropods was found by several research groups (Noguchi *et al.*, 1984; Hwang *et al.*, 2005; Huang *et al.*, 2008). The remaining specimen of poisoning *case 1* showed not high toxicity to compare with toxic snail species reported in Japan, which exhibited 4,290 MU/g (Taniyama *et al.*, 2008), but was more than the safety consumption level of TTXs (10 MU/g) suggested in Japan (Kodama and Sato, 2005), so still enough to cause human food poisoning. Based on the small amounts of TTXs and STXs detected in all specimens were provided from poisoning *case 2* and *case 3*, it is hard to explain food poisonings as these specimens may be considered as non-toxic. The present result is different from those analyzed on *Nassarius* sp. from Japan and Taiwan (Hwang *et al.*, 2005; Huang *et al.*, 2008), which was reported extremely high amount of TTX in the same species. Considering that the toxicity in marine snails has very large individual variation, for example, toxicity of *Alecton glans* in Japan could be ranged from 16 - 15,200 MU/g (Taniyama *et al.*, 2008), it is suggested that the toxicity of snail specimens which victims ate must be much higher than those examined in this study.

Further studies on the distribution of toxic snails and the mechanism of toxin accumulation in the snails are necessary for public awareness. It is urgent necessary to announce about potential risks from marine toxic snails to public as some of them may become toxic with unknown mechanism. It is should not eat any marine snail which was recorded as poisonous in other areas, or any strange marine snails.

Acknowledgement: We would like to thank Mr. Bui Quang Nghi, deputy head of Department of Museum and Conservation, Institute of Oceanography, Vietnam for species identification of snails. Also, our thank to Prof. Dr. Masaaki Kodama, School of Biosciences, Kitasato University and Prof. Dr. Yasuwo Fukuyo, Asian Natural Environmental Science Center, The University of Tokyo, Japan for revising of our manuscript.

ĐỘC TÍNH CỦA MỘT SỐ LOÀI ỐC BIỂN LIÊN QUAN ĐẾN CÁC VỤ NGỘ ĐỘC GẦN ĐÂY TẠI VIỆT NAM

ĐÀO VIỆT HÀ, SHIGERU SATO

Tóm tắt: Có ít nhất 5 vụ ngộ độc thực phẩm do ăn ốc biển được ghi nhận tại các vùng ven biển Việt Nam trong các năm 2006-2007. Mẫu vật ốc biển còn sót lại của 3 trong số 5 vụ ngộ độc này được xác định thuộc các loài *Nassarius papillosus*, *Nassarius (Alectrion) glans glans*, *N. (Zeuxis) comptus* và *Natica (Natica) fasciata*. Đây cũng là những loài gây ra những vụ ngộ độc tương tự ở một số Quốc gia khác như Nhật Bản, Phi-lip-pin, Brunây và Đài Loan.

Bằng phương pháp sắc ký lỏng hiệu năng cao (HPLC), đã xác định được hàm lượng khá cao độc tố tetrodotoxin (TTX) trong mẫu vật của loài *N. papillosus* gây ra vụ ngộ độc cho 3 nạn nhân (2 tử vong) ngày 17 - 10 - 2006 tại tỉnh Quảng Ngãi. Ngược lại, không tìm thấy sự có mặt của độc tố TTX trong 3 loài ốc biển nghi ngờ gây ra 2 vụ ngộ độc khác vào 17 - 12 - 2007 tại Ninh Thuận và 27 - 12 - 2007 tại Bình Thuận.

Mặc dù nguồn gốc của độc tố TTX trong ốc biển vẫn còn chưa được biết đến, nhưng một số loài ốc biển có thể trở nên độc một cách bất thường vào một thời điểm nhất định nào đó, do vậy cần thiết phải có cảnh báo về nguy cơ ngộ độc từ những loài sinh vật này.

Từ khóa: ngộ độc thực phẩm, ốc biển, *Nassarius*, *Nassarius*, *Natica*, tetrodotoxin.
